1 INTRODUCTION

This documentation provides a comprehensive guide for integrating the PS1-Styled Great White Shark into your development pipeline. It details the directory structures, and the strict technical rendering specifications required to maintain an authentic PS1 aesthetic. Furthermore, it outlines step-by-step engine configurations for Unity, Unreal Engine, and Godot. An exhaustive visual catalog of all included assets is provided at the end of this document for quick reference

2 CONTENT AND WORKFLOW

The geometry and textures are developed natively in **Blender 5.0.1**. The workflow ensures low polygon counts and vertex snapping compatibility characteristic of the targeted aesthetic.

2.1 Directory Structure

The package is organized into specific directories for optimized access.

Table 1: Correlation between folder names and their contents.

Folder Name	Description
GLB	Contains *.glb files with fully embedded textures
GLTF	Contains *.gltf files mapping to separated external texture files
OBJ	Contains *.obj static meshes and their corresponding material files
Previews	Contains previews of each asset, including metadata for polycount and object size
Textures	Contains the texture files

2.2 Blender Integration

The core ***.blend** file contains the source scene hosting all assets.

3 TECHNICAL SPECIFICATIONS

Default filtering methods (Bilinear/Trilinear) will blur the textures and compromise the pixelated aesthetic. To maintain the intended PS1 aesthetic and ensure seamless integration across different game engines, adhere to the following technical parameters:

Table 2: Recommended import and rendering settings.

Setting	Description
Metric Scale	Assets are modeled such that 1 Blender Unit $\equiv$ 1 Meter
Texture Filtering / Filter Mode	Set to Point (Unity/Unreal) or Nearest (Godot) or Closest (Blender). This ensures pixels are rendered sharply without interpolation
Mipmaps	Disable Generate Mipmaps. Mipmapping applies automatic blurring to textures viewed at a distance, which breaks the retro visual style
Texture Compression	Set to None or Uncompressed . Modern compression algorithms introduce blocky artifacts and color bleeding that degrade low-resolution textures
Normals / Shading	Set normals to Flat or disable Smooth Shading . Smooth normals interpolate lighting across polygon faces, which eliminates the faceted, low-poly geometry characteristic of PS1 hardware

3.1 Engine-Specific Configuration

The following configurations must be applied to every texture imported from this package. Default engine settings apply interpolation and compression that are incompatible with the PS1 aesthetic.

3.1.1 Unity

Select the texture asset in the Project panel. In the Inspector, apply the following settings under **Texture Import Settings**:

- **Filter Mode:** **Point (no filter)**
- **Generate Mip Maps:** Disabled
- **Compression:** **None**
- **Max Size:** Match the original texture resolution (maximum **256**)

For mesh shading, select the mesh and under **Model** $\rightarrow$ **Normals**, set **Smoothing Angle** to **0**.

3.1.2 Unreal Engine

Double-click the texture asset to open the Texture Editor. Apply the following settings in the **Details** panel:

- **Filter:** `Nearest`
- **Mip Gen Settings:** `NoMipmaps`
- **Compression Settings:** `UserInterface2D (RGBA)` or `TC_EditorIcon` to avoid lossy compression
- **sRGB:** Enabled (default)

For flat shading, set the Static Mesh **LOD** → **Normal Import Method** to `Import Normals` and ensure no smoothing groups are applied on export from Blender.

3.1.3 Godot

Select the texture file in the FileSystem dock and open the **Import** tab. Apply the following settings, then click **Reimport**:

- **Filter:** Disabled (corresponds to `Nearest` filtering)
- **Mipmaps** → **Generate:** Disabled
- **Compress** → **Mode:** `Lossless` or `Uncompressed`

Alternatively, set the **Texture Filter** property directly on the `MeshInstance3D` material to `Nearest` to override globally without reimporting each texture.
